

Overview

IOb-SoC is a RISC-V-based System-on-Chip Platform written in Verilog, which users can download for free, modify, simulate and implement in FPGA or ASIC. It supports stand-alone and boot loading modes. IOb-SoC can use an internal RAM or an external DDR controller via an L1/L2 cache system. The IP offers support for ASICs and FPGAs. Licensable commercial versions are available.

Features

- 32-bit RISC-V control CPU
- Support for Integer (I), atomic (A), and multiply/divide extensions (M)
- Instruction and data caches
- RS232 interfaces for viewing runtime messages
- Optional timer peripheral
- Optional Ethernet peripheral
- Frequency of operation at 167MHz on FPGA
- Needs external DDR4 memory controller IP

Benefits

- Compact and easy to integrate hardware and software implementation
- Can fit many instances in low-cost FPGAs and ASICs
- Low power consumption

Deliverables

- ASIC or FPGA synthesized netlist or Verilog source code, and respective synthesis and implementation scripts
- ASIC or FPGA verification environment by simulation and emulation
- Bare-metal software driver and example user software
- User documentation for easy system integration

Block Diagram

Implementation Results

The following are FPGA implementation results for two FPGA families. The results obtained use all the default user configurable parameters, which affect the RAM usage results.

Resource	Used	Resource	Used
LUTs	2072	ALM	1,542
Registers	1074	FF	1214
DSPs	4	DSP	3
BRAM	9	BRAM blocks	38
		BRAM bits	296,960
